PREFACE

THIS book is designed to be used in connection with college textbooks on finance, insurance and statistics. The steadily increasing number of students in colleges and universities pursuing courses in applied mathematics along one or more of these lines has created a demand for a book of tables including seven place logarithms of numbers to accompany the textbooks in these subjects.

If tables used in the examination room are in the textbook, it is difficult for the instructor to prepare a satisfactory examination, because many of the questions could be answered by direct reference to the textbook. If the necessary tables for numerical calculations are in a separate book, it may be used in the examination room. This leaves the instructor free to make his examination questions cover not only the theory in the textbook but also the solution of problems requiring consultation of tables and the ability to use them intelligently.

Although this book is sufficient for the requirements of college students, it is by no means limited in its use to their needs. An examination will show that it is of practical service to actuaries, statisticians, biometricians, engineers, astronomers, bankers and others who have occasion to make computations in interest, insurance and statistics.

Part I contains values of compound interest functions to eight places of decimals and seven place logarithms of values of compound interest functions for thirty-two rates of interest. Twelve of these rates under $1\frac{1}{8}\%$, inclusive, given for two hundred years, make it possible to solve many practical problems involving rates of interest compounded semi-annually, quarterly and monthly. The rates $7/24\%$, $5/12\%$, and $7/12\%$, for two hundred years, and the rates $1/3\%$ and $2/3\%$ for the second hundred years have not been published heretofore. A departure from the usual presentation is the inclusion of the sinking fund function, that is, the annuity which will amount to 1 at the end of n years.

A distinctive feature of these tables is the seven place logarithms of the values of the six compound interest functions. Logarithms to less than seven places would be useless, because most interest calculations arising in practice could not then be carried out to the nearest cent, and many not even to the nearest dollar.

The solution of problems often requires the values of compound interest functions for fractional periods, and no table would be complete which did not provide for the conversion of functions involving installment payments into one or more of the six tabular

functions. Comprehensive tables of values and logarithms of values of conversion factors, where $p=2$, 3, 4, 6, 12, 13, 26, 52, 365, ∞, are included for this purpose.

It sometimes happens that values are required to a larger number of decimal places than can be found in published tables. To meet this need and to aid in the construction of fundamental tables, the logarithm of the accumulation factor, $1+i$, is given to twenty decimal places for certain rates of interest.

Part II contains values of life insurance and disability insurance functions. Commutation columns based on the American Experience table of mortality with interest at 3%, 3½% and 4% enable the teacher to devise a variety of instructive problems in the calculation of values of annuity and insurance functions. They may also be used to compute functions not contained in these tables. The commutation columns based on the United States life tables at 5% serve a similar purpose.

The American Experience, 4%, accumulated value of 1, forborne life annuity due, single premium endowment insurance, single premium temporary insurance and temporary life annuity due, are included. With the aid of these tables the actuary and student can calculate terminal reserves, paid-up insurance values, pure endowment values and extended insurance values for any form of policy. The interest rate, 4%, was chosen because the values of these functions at 3% and 3½% have already been published in Dawson's Derived Tables.

Hunter's Makehamized American Experience table of mortality and commutation columns, 3½%, for two lives, equal ages, may be used to teach the student how to make calculations on joint lives.

The United States life tables for white males and for white females in the original registration states, 1910, are to acquaint the student with general mortality rates in this country.

Hunter's total and permanent disability tables are to familiarize the student with elementary calculations in connection with the disability provision in life insurance policies.

Part III contains tables of probability and statistical functions. One of the most important of these tables shows the area, ordinate, and second to eighth derivatives of the normal curve of error. It is more extensive than any other published table of these functions, and very useful in the application of the methods of Charlier to frequency curves. The logarithms of the Gamma Function serve the same purpose in connection with Pearson's frequency curves.

Newton's, Stirling's, Bessel's and Everett's interpolation coefficients are employed to compute the value of a function and its first derivative. Coefficients to express leading minor differences in terms of leading major differences for interpolating values between statistical ordinates are given for several types of formulas. The coefficients in Lubbock's summation formula are to facilitate the calculation of functions in statistical and actuarial theory. The table of logarithms of factorial n and a new table of logarithms of binomial coefficients are useful in the theory of probability.

The mean value table enables one to determine practically by inspection the exponential growth curve which most closely reproduces a series of statistical ordinates. It is the first table of this character which has been published covering any considerable range.

Part IV contains a seven place table of common logarithms of numbers from 1 to 100,000, also tables to convert common into natural and natural into common logarithms. They have been reproduced by photographic process from the well known manual of logarithms edited by Dr. Bruhns, which is practically free from error. These tables greatly reduce the labor of making calculations in compound interest and statistics and also enable the student to acquire some skill in the use of logarithms.

In the preparation of this book published tables have been edited and new tables computed. I desire to acknowledge the helpfulness of works which have been consulted, and to refer particularly to the following sources of information: Werker, Die zusammengesetzte Zinsen und Zeitrenten oder Annuitätenrechnung; Spitzer, Zinseszinsen und Rentenrechnung; Rice, Theory and Practice of Interpolation; Mantz, Joint Life Commutation Columns and Rates; Insurance Department of Wisconsin, Single Premium Temporary Insurance Tables.

I am indebted to my colleague, Professor Harry C. Carver, for valuable suggestions and aid in directing computation of tables, and to assistants without whom the lengthy calculations required would have been impossible.

The publication of so many tables necessarily involves the introduction of errors, and I shall be grateful for corrections received from those who use this book.

AGE INTERVAL.	OF 100,000 MALES BORN ALIVE:		RATE OF MORTALITY PER THOUSAND.	COMPLETE EXPECTATION OF LIFE.	STATIONARY MALE POPULATION, Unaffected by Emigration and Immigration, which, Assuming the Mortality Rates in Column 4, would result if 100,000 Males were Born Alive Uniformly Throughout Each Year.			
					POPULATION IN CURRENT AGE INTERVAL.	MEASURE OF VITALITY.	POPULATION IN CURRENT AND ALL OLDER AGE INTERVALS.	DEATH RATE PER THOUSAND.
Period of lifetime between two exact ages.	Number alive at beginning of age interval.	Number dying in age interval.	Number dying in age interval among 1,000 alive at beginning of age interval.	Average length of life remaining to those alive at beginning of age interval.	Including only those in current month or year of age.	Population per death in age interval.	Sum of numbers in column 6 in current and all older age intervals.	Average annual death rate per thousand living population in current and all older age intervals.

LIFE TABLE FOR WHITE FEMALES IN TH

BASED ON THE ESTIMATED POPULATION JULY 1, 1910 (11,706,221), AND ON TH

NOTE.—The original registration states include Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New York, New Jersey, Indian tables, are given

AGE INTERVAL.	OF 100,000 FEMALES BORN ALIVE:		RATE OF MORTALITY PER THOUSAND.	COMPLETE EXPECTATION OF LIFE.	STATIONARY FEMALE POPULATION, Unaffected by Emigration and Immigration, which, Assuming the Mortality Rates in Column 4, would result if 100,000 Females were Born Alive Uniformly Throughout Each Year.			
					POPULATION IN CURRENT AGE INTERVAL.	MEASURE OF VITALITY.	POPULATION IN CURRENT AND ALL OLDER AGE INTERVALS.	DEATH RATE PER THOUSAND.
Period of lifetime between two exact ages.	Number alive at beginning of age interval.	Number dying in age interval.	Number dying in age interval among 1,000 alive at beginning of age interval.	Average length of life remaining to each one alive at beginning of age interval.	Including only those in current month or year of age.	Population per death in age interval.	Sum of numbers in column 6 in current and all older age intervals.	Average annual death rate per thousand of population in current and all older age intervals.

Lubbock's formula in effect enables one to interpolate $n-1$ ordinates in each of m major intervals separating the equidistant statistical ordinates $u_0, u_1, \ldots\ldots u_m$, and obtain the sum of the original and interpolated ordinates. The sum of the ordinates separated by minor intervals is expressed in terms of the original major ordinates and their differences. It is necessary to know a sufficient number of major ordinates beyond u_m to calculate all the differences used.

If u_m and all ordinates beyond it are equal the formula simplifies considerably since all the differences of u_m then vanish. The formula is particularly useful in cases where u_m approaches zero asymptotically because then u_m and its differences become small and may be neglected. The sum of the ordinates obtained by Lubbock's formula may be used to obtain an approximate value of the area. For a full explanation and examples illustrating the application of the formula consult the Text Book of the Institute of Actuaries, Part II, pages 467-474.

$$\log\,\Gamma(n+1)=\log\,n+\log\,\Gamma(n)$$

EXPONENTIAL GROWTH CURVE THEORY

The exponential growth curve

$$y = a\,r^{x}$$

can be fitted to serial data by taking the position of the first term as origin and assuming the conditions

$$\sum_{i=0}^{n-1} y_i = \sum_{i=0}^{n-1} {}_{o}y_i = \mathbf{N}, \qquad \sum_{i=0}^{n-1} x_i y_i = \sum_{i=0}^{n-1} x_i \cdot {}_{o}y_i,$$

where ${}_{o}y_i$ denotes the observed frequency.

$$\text{Then} \quad \sum_{i=0}^{n-1} y_i = a \sum_{i=0}^{n-1} r^{i} = a\frac{r^{n}-1}{r-1},$$

$$\text{and} \quad \sum_{i=0}^{n-1} x_i y_i = a \sum_{i=0}^{n-1} x_i r^{i} = a\left[(n-1)\frac{r^{n}}{r-1} - \frac{r^{n}-r}{(r-1)^{2}}\right].$$

Hence the value of the mean, M, may be written

$$\mathbf{M} = \sum_{i=0}^{n-1} x_i \cdot {}_{o}y_i \Big/ \sum_{i=0}^{n-1} {}_{o}y_i = \frac{n}{1-r^{-n}} - \frac{1}{1-r^{-1}}.$$

The following table has been prepared which enables one to obtain the value of r by inspection when M and n are known. After r is determined, a is computed by the formula

$$a = \frac{r-(n-\mathbf{M})(r-1)}{n}\mathbf{N}.$$

The method commonly used of fitting the logarithms of the frequencies to the straight line is open to several objections. The sum of the logarithms of the frequencies, that is, the product of the frequencies, is reproduced, instead of the desired sum of the frequencies themselves. Furthermore, the fact that the linear method yields the best fit to the logarithms means that it does not give the best fit to the frequencies themselves. Too much weight is given to the smaller frequencies.

Mean Value Table to Fit Exponential Growth Curve $y = ar^x$ to n Observed Statistical Ordinates

$$M = \sum_{0}^{n-1} x_i \cdot {}_o y_i \Big/ \sum_{0}^{n-1} {}_o y_i = n/(1-r^{-n}) - 1/(1-r^{-1})$$
